ARXON

Sovereign Privacy Blockchain
for the Unbanked World

LITEPAPER

2026

arxon.io

"Financial sovereignty is not a privilege. It is a right."

This document is a clear, honest overview of what Arxon is, what problem it solves, and what we are building. It is written for anyone, not just developers or investors. If you have ever sent money across borders, worried about who can see your finances, or wondered whether your vote actually counts, Arxon is built for you.

The Problem

The global financial system was not built for everyone. Despite two generations of cryptocurrency innovation, over 1.4 billion adults worldwide remain without access to basic financial services.

Blockchain promised to change this. In practice, the benefits have mostly flowed to those who were already financially included.

Three specific problems remain unsolved:

Financial Exclusion

Hundreds of millions of people in Africa, Asia, and Latin America conduct their entire financial lives in cash. Without bank accounts, they cannot save securely, access credit, or participate in the digital economy. Traditional banks require government ID, proof of address, minimum balances, and physical branches, requirements that exclude entire communities.

Financial Surveillance

Public blockchains solve financial exclusion but introduce a new problem: total transparency. On most chains, your wallet balance, every transaction you have ever made, and every person you have ever paid is permanently visible to anyone on earth. In environments where wealth makes you a target, or where political activity can lead to persecution, a fully transparent financial record is dangerous.

The Cost of Sending Money Home

The Nigerian diaspora alone sends over $20 billion home every year. At current average fees of 6-8% charged by services like Western Union, that means over $1.5 billion is extracted from the world's poorest families every single year, not going to the families, not going to the economy, just disappearing into fees. Blockchain can reduce this cost to near zero. But only if the technology is actually accessible.

Existing privacy blockchains do not solve this well. Some force every transaction to be anonymous whether you want it or not, creating regulatory problems and exchange delistings. Others offer a simple on/off switch that most users never touch. None offer what real people actually need: control over exactly what information they share, with whom, and when.

The Arxon Solution

Arxon is a sovereign Layer-1 blockchain built from the ground up to serve the people that existing financial systems, both traditional and crypto, have failed. It is not a modification of another chain. It is not built on Ethereum or Bitcoin. Arxon is its own independent network with its own consensus, its own token, its own rules, and its own mission.

Arxon gives users complete control over their financial privacy, not a binary switch, but granular, per-transaction choice.

The core innovation is the Selective Privacy System. Every transaction on Arxon carries four independent privacy flags. A user can choose any combination:

- Hide the sender address
- Hide the receiver address
- Hide the transaction amount
- Hide their wallet balance from public view

This means a Nigerian woman receiving money from her son in London can show who sent it, so she knows it is genuine but hides the amount, so no one in her community knows her financial situation. A business paying a supplier can make the payment amount private for competitive reasons while keeping the destination publicly verifiable. A voter casting a ballot can hide everything about their participation while still being able to prove they voted if they choose to.

No other blockchain offers this level of user control. Arxon is the first.

What Arxon Has Built

Arxon is not a concept or a whitepaper project. The chain is running. Blocks are being produced. Transactions are being processed. Here is what exists today:

A Live Sovereign Blockchain

Arxon runs its own independent network using BABE/GRANDPA consensus, the same battle-tested mechanism that secures Polkadot, one of the largest blockchain ecosystems in the world. The chain produces a new block every six seconds. It has been running in multi-node testnet configuration with independent validators producing and finalising blocks in real time.

The chain has its own unique identity: Unique Chain ID, token symbol (ARX), and total supply which is fixed, with no inflation.

Full Ethereum Compatibility

Arxon is fully compatible with the Ethereum Virtual Machine. This means any smart contract written for Ethereum deploys on Arxon without a single line of code changed. MetaMask connects to Arxon. Every Ethereum developer tool works on Arxon out of the box. This opens Arxon to the entire Ethereum ecosystem of developers, protocols, and applications, on day one.

The combination of Ethereum compatibility with Arxon's selective privacy creates something that does not exist anywhere else: privacy-preserving decentralised finance. A DeFi protocol on Arxon can accept private payments, offer hidden balances, and execute confidential transactions, while remaining accessible through MetaMask like any standard Ethereum dApp.

The Selective Privacy System

The privacy pallet is live on-chain. Users can set their default privacy preferences for all future transactions or configure privacy on a per-transaction basis. The four flags (hide sender, hide receiver, hide amount, hide balance), work independently and in any combination. Eight distinct privacy modes emerge from these four flags, from fully transparent to fully shielded.

The current implementation stores privacy preferences on-chain and enforces them at the application layer. The next phase adds zero-knowledge cryptographic proofs, mathematical guarantees that hidden information cannot be revealed even by examining the chain's raw data.

Private Transaction Receipts

Every transaction with any privacy flag active automatically generates a Private Transaction Receipt, a tamper-proof, permanently stored record of the full transaction details. This receipt is a legal document. It contains the complete sender address, receiver address, transaction amount, timestamp down to the second, block number, and crucially, each party's wallet balance immediately before and after the transaction.

The balance information is split: the sender sees their own balance history on their receipt, the receiver sees their own. Neither sees the other's balance. This snapshot reflects the exact moment

of the transaction, not the current balance and cannot be altered because it is written permanently to the blockchain.

When a dispute arises, in a court, a business negotiation, or any formal setting either party can produce their receipt. If two receipts share the same transaction hash, the transaction is proven beyond question. No private keys need to be shared. No seed phrases need to be revealed. The receipt itself is the evidence.

For situations requiring third-party verification, either party can generate a single-use disclosure code. This code grants one-time access to the full transaction details including both parties' balance snapshots. The code burns permanently after use. Either party can generate as many separate codes as needed, one for a lawyer, one for a judge, one for a regulator, each working exactly once. Every code generated and used is logged permanently on-chain.

The ARX-P Mining System

Before mainnet launches, Arxon has built a mining community of 14k+ users growing toward the target of at least 500k-1M active miners. These are real people, earning real points through browser and mobile mining applications (Coming soon) that require no hardware investment and no technical knowledge. Anyone with a phone can participate.

Points earned through mining are called ARX-P. At mainnet, these points convert to real ARX tokens through the on-chain claim system.

This approach to community building is intentional. Most blockchain projects launch and then struggle to acquire users. Arxon's mining community means there will be immediate organic demand for ARX at launch from hundreds of thousands of real participants who earned their tokens through effort, not through purchasing power.

The ARX Claim System

The on-chain claim pallet handles the conversion of ARX-P points to ARX tokens at mainnet. It is built to handle unlimited claimants whether 100,000 or 10,000,000 with the same on-chain efficiency. A snapshot of all point balances is taken, loaded on-chain, and each miner calls the claim function exactly once to receive their ARX. The process is transparent, verifiable, and cannot be manipulated after the snapshot is locked.

What We Are Building

Arxon's current state is the foundation. What is being built on top of it is where the mission becomes clear.

Zero-Knowledge Cryptographic Privacy

The privacy system today works at the application layer. The next phase adds Halo2 zero-knowledge proofs, a mathematical system that makes hidden information impossible to reveal, even with complete access to the blockchain's raw data. When a user hides an amount, a ZK proof mathematically guarantees that the hidden amount satisfies all the rules of a valid transaction without revealing what it is. This is not an approximation of privacy. It is cryptographic certainty.

Halo2 was chosen specifically because it requires no trusted setup. In most ZK systems, a group of people must perform a ceremony to generate parameters, and the security of the entire system depends on at least one of them having deleted their secret. Halo2 eliminates this requirement entirely, the security is mathematical, not ceremonial.

On-Chain Private Voting

Democratic elections face a fundamental problem that paper ballots cannot solve: coercion. In traditional voting, a powerful actor, an employer, a spouse, or a political party can demand to see proof of how someone voted, or threaten consequences if a receipt is not produced. Arxon's voting system makes coercion cryptographically impossible.

The system works through a mathematical mechanism called a nullifier. A voter proves they are eligible to vote without revealing who they are. They cast their vote in a way that proves it is valid, for a real candidate, from an eligible voter, showing the candidate they chose without revealing their full identity to the public. A receipt proves they voted, proves the party they voted for, but cannot prove to any party the name of the candidate they voted for, even under legal compulsion.

Results are tallied through Layer-2 zero-knowledge batch proofs. A batch of 100,000 votes generates a single proof that the aggregate is correctly computed, and that proof is submitted to the Arxon chain. One billion votes across 10,000 batches settles on-chain in seconds. The mathematics of ZK scaling mean that any election from a local community vote to a national election with hundreds of millions of participants, is within reach.

The Developer Ecosystem

Because Arxon is fully EVM-compatible, every Ethereum developer can build on it today. The vision for the Arxon developer ecosystem includes:

- **Privacy-preserving DeFi** — trading, lending, and liquidity with confidential amounts
- **Private remittance applications** — send money home with hidden amounts and verifiable delivery
- **Confidential payroll systems** — employees paid in ARX with private salary information
- ZK voting applications for communities, DAOs, and governments
- **Private NFT marketplaces** — prove ownership without revealing purchase price
- **Confidential identity systems** — prove eligibility without revealing personal data

These applications are not possible on any other EVM-compatible chain at this level of granularity. Arxon is the only platform where an Ethereum developer can build a product with per-transaction selective privacy on day one.

Roadmap

The following reflects what has been completed and what is being actively built. Arxon will publish its progress openly on GitHub. Every milestone listed below corresponds to working code, not plans.

COMPLETE Foundation	→ Sovereign Layer-1 blockchain running in multi-node testnet → ARX native token, fixed supply → Full EVM compatibility - MetaMask, Solidity, all Ethereum tooling → Selective privacy system - four independent per-transaction flags → Balance visibility toggle - users control public/private balance display → Private Transaction Receipt system with single-use disclosure codes → ARX-P mining system - community earning before mainnet → On-chain ARX claim pallet for unlimited miners → Node branding, validator infrastructure, testnet chainspec → Professional whitepaper and open-source codebase on GitHub
IN PROGRESS Public Testnet	→ Public testnet launch - anyone can connect and transact → Block explorer - browse all Arxon transactions publicly → Testnet faucet - developers get test ARX to build with → Validator expansion - growing the independent validator set

	→ Anti-rug protection registry for builders → Developer documentation and SDK release → MetaMask official chain registration
BUILDING ZK Privacy	→ Halo2 zero-knowledge proof integration for private transfers → Cryptographic enforcement of all four privacy flags → ZK voting Phase 1 - private on-chain votes with verifiable results → Privacy-preserving DeFi primitive contracts → Third-party ZK circuit security audit
AHEAD Ecosystem	→ ZK voting Phase 2 - national-scale batch proof elections → Remittance corridor integrations for Nigeria and diaspora markets → Mobile wallet with built-in privacy controls → Institutional partnerships for election infrastructure → Cross-chain bridges to major ecosystems → Mainnet launch with ARX-P conversion open to all miners

Why Arxon

There are hundreds of blockchain projects. Most of them are solving problems that already have solutions, for users who are already served by existing systems. Arxon is different in three ways that matter.

The problem is real and the users are real

Financial exclusion is not a theoretical problem. It affects hundreds of millions of people right now. The diaspora sending money home, paying 7% in fees, is real. The person in a country with unstable governance who cannot safely show their wealth is real. The voter who fears coercion is real. Arxon is built for these people, not as a marketing narrative, but as the actual design brief.

The technology is original

Selective transaction privacy, the ability to independently hide sender, receiver, amount, and balance on a per-transaction basis, does not exist on any other production blockchain. This is not an incremental improvement. It is a new capability. As we build with zero-knowledge proofs, Arxon becomes the most sophisticated privacy system on any EVM-compatible chain.

A Final Word

Bitcoin proved that money without banks was possible. Ethereum proved that programmable money was possible. Arxon is proving that private, accessible, fair money is possible and building it for the people who need it most.

The chain is running. The community is growing. What comes next is the ecosystem (the developers, the applications, the elections, the remittances, and the millions of people) who will use Arxon without knowing or caring about the technology underneath, only that it works, that it is fair, and that it is theirs.

"Arxon is Built For the world."
